## MATH2089 – Numerical Methods

### Week 03 – Nonlinear equations - II

- 1 Newton's method
- 2 Secant method

- 3 Convergence
- 4 Rate of convergence

- MATLAB M-files

- `nlog2n_newton.m`      `nthroot.m`
- `nle1.m` `nle2.m`      `pltsin.m`

## Newton's method

- Requires function value  $f(x)$  and its derivative  $f'(x)$
- First order Taylor series approximation of  $f$  about  $x_k$  gives

$$f(x) \approx f(x_k) + (x - x_k)f'(x_k).$$

- Choose the next point  $x_{k+1}$  to make right-hand-side zero

- Newton's method

$$x_{k+1} = x_k - \frac{f(x_k)}{f'(x_k)}.$$

- Assumes that the first derivatives  $f'(x_k) \neq 0$
- Fast rate of convergence in the neighbourhood of a simple zero.
- MATLAB M-file `nlog2n_newton.m`

## Geometrical interpretation

## Example

Formulate Newton's method for solving  $x \log_2(x) = c$  for some constant  $c > 0$ .

## Example

Formulate Newton's method for finding the  $n$ root of  $a > 1$  for some integer  $n > 1$ .

## Secant method

- Difficulties with Newton's method
  - need to calculate derivative  $f'(x)$
  - possibly dividing by zero if  $f'(x_k) = 0$  for some  $k$ .
- Derivatives
  - **Symbolic algebra packages:** MAPLE, MUPAD, MATHEMATICA
  - **Automatic differentiation:** computer program: input your program to evaluate  $f(x)$ ; output a program to evaluate the derivative  $f'(x)$
  - **Finite difference approximation** using values at  $x_k, x_{k-1}$

$$f'(x_k) \approx \frac{f(x_k) - f(x_{k-1})}{x_k - x_{k-1}}.$$

- **Secant condition**

$$f'(x_k)(x_k - x_{k-1}) = f(x_k) - f(x_{k-1})$$

- **Secant method** Replace  $f'(x_k)$  in Newton's method

$$x_{k+1} = x_k - \frac{f(x_k)(x_k - x_{k-1})}{f(x_k) - f(x_{k-1})}$$

## Secant method cont.

- Secant method

$$x_{k+1} = \frac{f(x_k)x_{k-1} - f(x_{k-1})x_k}{f(x_k) - f(x_{k-1})}$$

- Only requires function values
- Equivalent to approximating function by line through

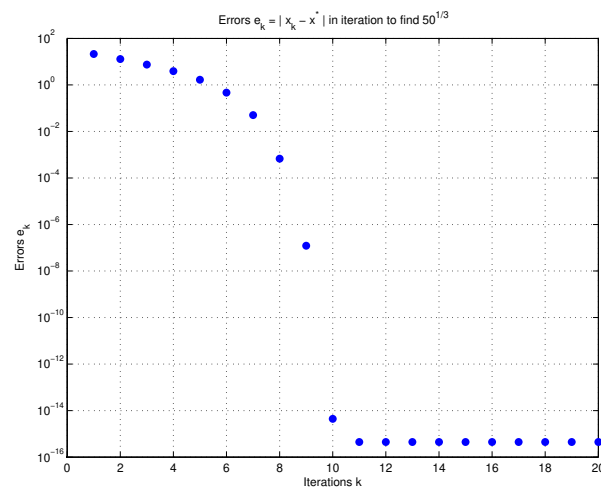

$$(x_{k-1}, f(x_{k-1})), \quad \text{and} \quad (x_k, f(x_k)).$$

- Requires two starting points  $x_0, x_1$

**Question** Which method is the fastest, which method is the slowest ?

## Errors

- Errors  $e_k = |x_k - x^*|$ .
- Convergence as  $k \rightarrow \infty$ :  $x_k \rightarrow x^* \iff e_k \rightarrow 0$

## Iterative methods and convergence

### Iterative methods

- Starting point  $x_1$
- Generate a sequence of iterates  $x_k$ ,  $k = 2, 3, \dots$
- Notation:  $f_k \equiv f(x_k)$

- Convergence**  $\lim_{k \rightarrow \infty} x_k = x^*$  where  $f(x^*) = 0$ .

- $f$  is continuous then

$$\lim_{k \rightarrow \infty} f_k = 0$$

- Practical convergence:** tolerances  $\tau$

- $|x_k - x^*| < \tau$  **Don't know  $x^*$**
- $|x_{k+1} - x_k| < \tau_x$  convergence  $\implies |x_{k+1} - x_k| \rightarrow 0$
- $|f_k| < \tau_f$
- Maximum number of iterations

## Rate of convergence

- How quickly does  $x_k \rightarrow x^*$ ? (or equivalently  $e_k \rightarrow 0$ )

### Definition (Order of convergence)

The **order of convergence** is the largest  $\nu$  such that

$$\lim_{k \rightarrow \infty} \frac{|x_{k+1} - x^*|}{|x_k - x^*|^\nu} < \infty$$

- Linear or first order convergence**  $\iff \nu = 1$

$$\lim_{k \rightarrow \infty} \frac{|x_{k+1} - x^*|}{|x_k - x^*|} = \beta, \text{ where } 0 < \beta < 1$$

- Rate constant  $0 < \beta < 1$  is critical
- $\beta$  close to 1, eg  $\beta = 0.99$  very slow
- $\beta = 0.1 \implies$  reduce error by 10 on each iteration.

- Super-linear** convergence order  $\iff 1 < \nu < 2$

- Quadratic** convergence order  $\iff \nu = 2$

- MATLAB M-file [nlog2n.m](#)

## Rates of convergence II

- Convergence  $e_k \rightarrow 0$
- Linear convergence, rate  $\beta$  (order of convergence  $\nu = 1$ )

$$\frac{e_{k+1}}{e_k} \rightarrow \beta \in (0, 1), \quad \frac{e_{k+1}}{(e_k)^2} \rightarrow \infty$$

- Super-linear convergence (order of convergence  $1 < \nu < 2$ )

$$\frac{e_{k+1}}{e_k} \rightarrow 0, \quad \frac{e_{k+1}}{(e_k)^2} \rightarrow \infty$$

- Quadratic convergence (order of convergence  $\nu = 2$ )

$$\frac{e_{k+1}}{e_k} \rightarrow 0, \quad \frac{e_{k+1}}{(e_k)^2} \rightarrow K \in (0, \infty), \quad \frac{e_{k+1}}{(e_k)^3} \rightarrow \infty$$

- Example: MATLAB `nlog2n.m`

## Convergence of Newton's method

### Proposition (Convergence of Newton's method)

$f$  twice continuously differentiable,  $x^* : f(x^*) = 0$  and  $f'(x^*) \neq 0$   
 $x_1$  sufficiently close to  $x^* \implies$  Newton's method is well-defined and converges to  $x^*$  with a **second order** rate of convergence.

## Convergence of fixed point iteration

### Proposition

- $g \in C([a, b])$  and  $g(x) \in [a, b]$  for all  $x \in [a, b] \implies g$  has a fixed point in  $[a, b]$
- $g \in C^1((a, b))$  and  $\exists K : 0 < K < 1$  with  $|g'(x)| \leq K \forall x \in (a, b) \implies$  fixed point iteration converges **linearly** for any  $x_1 \in [a, b]$

## Convergence of secant method

### Proposition

Suppose  $f$  is continuously differentiable, and  $f$  has a simple zero  $x^*$ , i.e.  $f(x^*) = 0$  and  $f'(x^*) \neq 0$ .

- The secant method has a **super-linear** rate of convergence.
- Order of convergence is  $\nu = (1 + \sqrt{5})/2 \approx 1.618$

## Rates of convergence III

### Example (Rate of convergence)

If  $|x_1 - x^*| \approx 0.1$  estimate how many iterations it will take to get  $|x_{k+1} - x^*| < 10^{-14}$  using a method

- ➊ linearly convergent with rate  $\beta = 0.99$
- ➋ linearly convergent with rate  $\beta = 0.1$
- ➌ super-linearly convergent with order  $\nu = 1.5$
- ➍ quadratically convergent
- ➎ third order method

### Solution
